**Keywords:** Honey, Ancient remedy, Cancer, Immune booster, Anti-inflammatory, Anti-microbial, Natural cancer vaccine

### Abstract

During ancient times, honey has been used for all kinds of ailments and for cosmetic purposes. This review focusses on characteristics of honey in combating cancer after understanding the risk factors of cancer. Honey could be considered the most sustainable food produced naturally. It contains sugars, vitamins, minerals and has high anti-oxidant activities. Cancer is on the rise in most countries. Carcinogenesis is a multi-step process and has multi-factorial causes. Among these are low immune status, chronic infection, chronic inflammation, chronic nonhealing ulcers, smoking, obesity etc. Published studies thus far have shown that honey improves immune status, has anti-inflammatory and anti-microbial properties and promotes healing of chronic ulcers and wounds and scavenge toxic free radicals. Recently several studies have shown that have anti-cancer properties in cell cultures and in animal models. The mechanisms suggested include induction of apoptosis, disruption of mitochondrial membrane potential and cell cycle arrest. Though sugar is predominant in honey which itself is thought to be carcinogenic, it is understandable that its beneficial effect as anti-cancer agent raises skeptics. With increasing number of people seeking therapy from nature, this area of research has recently gained attention. However, using honey alone as treatment without adequate treatment with established anticancer treatment for now is not ethical. Honey however could reduce the risk factors for cancer development thus it is a possible natural cancer vaccine.

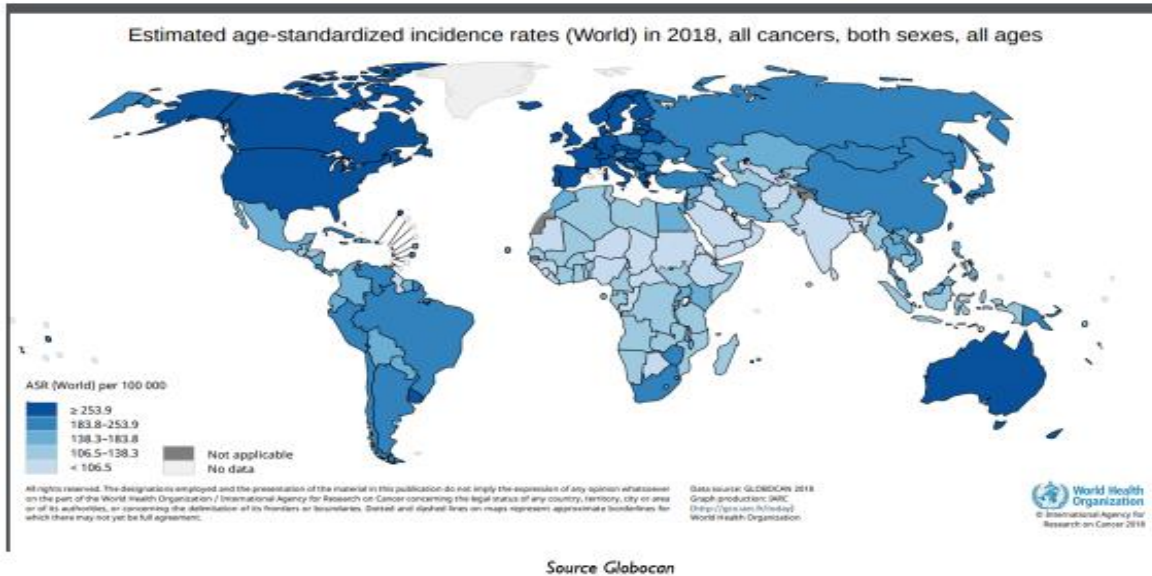

### Cancer – the Global Burden

According to the International agency against cancer [IARC, it is stated that the global cancer burden was 18.1 million cases and 9.6 million cancer deaths in 2018 [Figure 1]. Cancer was seen in one-in-five men and one-in-six women worldwide. The increase in populations was much more in developing countries than in developed countries. Even if the age-specific rates of cancer remain constant, developing countries would have a higher cancer burden than developed countries. Cancers which are associated with diet and life-style are seen more in developed countries while cancers which are due

to infections are more in developing countries. According to World Health Organization (WHO), death from cancer is expected to increase to 104% worldwide by 2020.

In order to understand the usefulness of honey in cancer, we need to understand the various factors which could cause cancer. Carcinogenesis is a multi-step process and cancer has multi-factorial causes. Development of cancers takes place long after initiation, promotion and progression steps have taken place. Cancer development could occur 10-15 years after exposure to the risk factors.

## World Cancer Burden 2018

**Figure 1.** Estimated new cancer cases by world for 2018 (source: Globocan, 2018)

### Causes of Cancer:

The causes of cancer can be categorized as follows:-

1. Low immune status eg due to diabetes, chronic illness, obesity and old age
2. Chronic infections such as by bacteria *helicobacter pylori* (cancer of the stomach), viruses such as Human Papilloma Virus (cancer of the cervix, skin and penis), Epstein Barr Virus (nasopharyngeal carcinoma), Hepatitis viruses such as Hepatitis B, C (hepatocellular carcinoma); parasites such as shistosomiasis (bladder cancer) and fungus such as *Aspergillus flavus* (hepatocellular carcinoma)
3. Chronic inflammation, for example colorectal cancer developing in patients with Crohns colitis and ulcerative colitis.
4. Chronic non healing ulcers, for example squamous cell carcinoma developing in patients with chronic traumatic ulcers of the skin.
5. Accumulation of toxic free radicals and oxidative stress secondary to smoking, alcohol, obesity and chronic inflammatory processes
6. Genetic inheritance
7. Unknown – there is still a lot we do not know and I term this GOK [God only knows] in this paper

Cancer is caused by genetic damage in the genome of cells. This damage is either inherited or acquired throughout life. The acquired genetic damage is often ‘self-inflicted’ through unhealthy lifestyles. Broadly one third of cancer is due to tobacco use, one third due to dietary and lifestyle factors and one-fifth due to infections. In developing countries, cancers caused by infections by micro-organisms such as cervical (by Human Papilloma Virus) (Parkin et al., 2008), liver (by Hepatitis Viruses) (Yuen et al., 2009), nasopharynx (by Epstein Barr Virus) (Chou et al., 2008) and stomach (by *helicobacter pylori*) (Kuniyasu et al., 2003) are more common than in developed countries (DCP2, 2007). Except for breast cancers, the top 5 cancers in males and females in developing nations are due to life-styles or infections (DCP2, 2007).

### Why is Honey Useful in Preventing Cancer?

Honey is known for centuries for its medicinal and health promoting properties. It contains various kinds of phytochemicals with high phenolic and flavonoid content which contribute to its high antioxidant activity (Iurlina et al., 2009; Pyrzyńska and Biesaga, 2009; Yao et al., 2003). An agent that has strong antioxidant property may have the potential to prevent the development of cancer as free radicals and oxidative stress play a significant role in inducing the formation of cancers (Valko et al., 2007). Phytochemicals available in honey could be narrowed down into phenolic acids and polyphenols. Variants of

polyphenols in honey are reported to have anti-proliferative property against several types of cancer (Jaganathan and Mahitosh, 2009).

### Honey is a natural immune booster

Honey stimulates antibody production during primary and secondary immune responses against thymus-dependent and thymus-independent antigens in mice injected with sheep red blood cells and E-coli antigen (Al-Waili and Haq, 2004). Oral intake of honey augments antibody productions in primary and secondary immune responses (Fukuda et al., 2009). Honey also stimulates inflammatory cytokine production from monocytes (Tonks et al., 2003) via TLR4 (Tonks et al., 2007). Manuka, pasture and jelly bush honey significantly increased TNF- $\alpha$ , IL-1 $\beta$  and IL-6 release from MM6 cells (and human monocytes) when compared with untreated and artificial-honey-treated cells (P<0.001) (Tonks et al., 2003). Consumption of 80 g natural honey for 21 days raised prostaglandins level in patients with AIDS compared with normal subjects (Al-Waili et al., 2006).

Patients who have compromised immune systems are at risk for cancer development. This explains why diabetics and HIV patients are more at risk to develop epithelial and non-epithelial cancers. Such individuals are also at risk to develop multiple chronic infections implying the multiplicity in cancer genesis.

Aging is also associated with reduced immune system capability. Many cancers are associated with aging. Although age per se is not an important determinant of cancer risk, it implies prolonged exposure to carcinogen (Franceschi and La Vecchia, 2001). The most important change that would occur in the world population in the next 50 years is the change in the proportion of elderly people (more than 65 years); 7% in 2000 to 16% in 2050 (Bray and Moller, 2006). By the year 2050, 27 million people are projected to have cancer. More than half of the estimated number will be residents of developing countries (Bray and Moller, 2006). Improvement in immune status is key in prevention of cancer formation and honey has such potential.

### Honey is a natural anti-inflammatory agent

In general inflammatory responses are beneficial, but at times, chronic inflammatory responses are detrimental to health. Honey is a potent anti-inflammatory agent. Infants suffering from diaper dermatitis improved significantly after topical application of a mixture containing honey, olive oil and beeswax after 7 days (Al-

Waili, 2005). Honey provides significant symptom relief of cough in children with upper respiratory tract infection (URTI) (Heppermann, 2009). It has been shown to be effective in management of dermatitis and psoriasis vulgaris (Al-Waili, 2003). Eight out of 10 patients with dermatitis and five of eight patients with psoriasis showed significant improvement after 2 weeks on honey-based ointment (Al-Waili, 2003).

A case report of a patient who had chronic dystrophic epidermolysis bullosa (EB) for 20 years healed with honey impregnated dressing in 15 weeks after conventional dressings and creams failed (Hon, 2005). Local application of raw honey on infected wounds reduced signs of acute inflammation (Al-Waili, 2004b), thus alleviating pain felt by patients.

Volunteers who chewed "honey leather" showed there were statistically highly significant reductions in mean plaque scores (0.99 reduced to 0.65; p=0.001) in the manuka honey group compared to the control group suggesting a potential therapeutic role of honey for gingivitis, periodontal disease (English et al., 2004), mouth ulcers, and other problems of oral health (Molan, 2001b).

Chronic inflammatory process has risk of cancer development. Examples of cancers developing in patients suffering from chronic inflammatory processes include colorectal carcinomas developing in patients with Ulcerative Colitis and Chron's disease and thyroid cancers in patients with autoimmune thyroiditis.

### Honey is natural antimicrobials

Honey is a potent natural antimicrobial. Antibacterial effect of honey is extensively studied. The bactericidal mechanism is through disturbance in cell division machinery (Henriques et al., 2009). The minimum inhibitory concentration (MICs) for *Staphylococcus aureus* by honey ranged from 126.23 to 185.70 mg ml(-1) (Miorin et al., 2003). Honey is also effective against coagulase-negative staphylococci (French et al., 2005). Antimicrobial activity of honey is stronger in acidic media than in neutral or alkaline media (Al-Waili, 2004b). When honey is used together with antibiotic gentamycin, it enhances anti-*Staphylococcus aureus* activity by 22% (Al-Jabri et al., 2005). When honey is added to bacterial culture medium, the appearance of microbial growth on the culture plates is delayed (Al-Waili et al., 2005). Mycobacteria did not grow in culture media containing 10% and 20% honey while it grew in culture media containing 5%, 2.5% and 1% honey,

suggesting that honey could be an ideal antimycobacterial agent (Asadi-Pooya et al., 2003) at certain concentrations.

Honey is also effective in killing hardy bacteria such as *Pseudomonas aeruginosa* and could lead to a new approach in treating refractory chronic rhino-sinusitis (Alandejani et al., 2009). Daily consumption of honey reduces risk of chronic infections by micro-organisms.

Chronic infections lead to greater risk in cancer development.

Bacteria which have been studied to have associations with cancer are *helicobacter pylori* infections (stomach cancer) (Kuniyasu et al., 2003), *Ureaplasma urealyticum* (prostate cancer) (Hrbacek et al., 2011) and chronic typhoid infection (gall bladder cancer) (Sharma et al., 2007).

There are three main mechanisms by which infections can cause cancer. They appear to involve initiation as well as promotion of carcinogenesis (Kuper et al., 2001). Persistent infection within host induce chronic inflammation accompanied by formation of reactive oxygen and nitrogen species (ROS and RNOS) (Kuper et al., 2001). ROS and RNOS have the potential to damage DNA, proteins and cell membranes. Chronic inflammation often results in repeated cycles of cell damage leading to abnormal cell proliferation (Cohen et al., 1991). DNA damage promotes the growth of malignant cells. Secondly, infectious agents may directly transform cells, by inserting active oncogenes into the host genome, inhibiting tumour suppressors (Kuper et al., 2001). Thirdly, infectious agents, such as human immunodeficiency virus (HIV), may induce immunosuppression (Kuper et al., 2001).

Chronic fungi infections have also been studied to be associated with cancer such as candida species in oral cancer (Hooper et al., 2009). Honey has been shown to have some effect on chronic fungal infections of the skin (Al-Waili, 2004a). Parasites such as *Schistosoma haematobium* are associated with carcinoma of the urinary bladder, liver flukes *Opisthorchis viverrini* and *Clonorchis sinensis* are associated with development of cholangiocarcinoma and hepatocellular carcinoma. Thus far, there are no published reports on effect of honey on parasitic diseases.

Besides bacteria, honey has also been shown to have anti-viral properties. In a comparative study, topical application of honey was found to be better than

#### Honey is a 'fixer' for chronic ulcers and wounds

acyclovir treatment on patients with recurrent herpetic lesions (Al-Waili, 2004c). Two cases of labial herpes and one case of genital herpes remitted completely with the use of honey while none with acyclovir treatment (Al-Waili, 2004c).

Common viruses which cause cancers (Carrillo-Infante et al., 2007) are Epstein-Barr virus (EBV) (Siddique et al., 2010) (nasopharyngeal carcinomas), Human Papilloma Virus (cervical cancers and other squamous cancers) and Hepatitis B viruses (liver cancers). Viruses are oncogenic after long period of latency (McLaughlin-Drubin and Munger, 2008).

Studies on the effect of honey on these specific viruses are required to affirm the usefulness of honey in combating cellular damage caused by these viruses.

#### Honey is a scavenging agent of toxic free radicals

The link between cancer and cigarette smoking is beyond doubt. It is due to generations of toxic free radicals and oxidative stress. Smoking is associated with a number of cancers such as larynx, bladder, breasts, oesophagus and cervix. Smoking increases the risk of colorectal carcinomas by 43% (Huxley, 2007). Long-term smokers were associated with an 8.8-fold increased risk of colorectal cancers (95% confidence interval, 1.7-44.9) when fed on well-done red meat diet if they have NAT2 and CYP1A2 rapid phenotypes (Le Marchand et al., 2001).

Antioxidants, abundant in natural honey, are free radical scavengers (Kishore et al., 2011). Jungle honey was shown to have chemotactic induction for neutrophils and reactive oxygen species (ROS) (Fukuda et al., 2009). The amino acid composition of honey is an indicator of the toxic radical scavenging capacity (Perez et al., 2007). The antioxidant activity of *Trigona carbonaria* honey from Australia is high at 233.96 +/- 50.95 microM Trolox equivalents (Oddo et al., 2008). Dark honey had higher phenolic compounds and antioxidant activity than clear honey (Estevinho et al., 2008). Some simple and polyphenols found in honey, namely, caffeic acid (CA), caffeic acid phenyl esters (CAPE), Chrysin (CR), Galangin (GA), Quercetin (QU), Kaempferol (KP), Acacetin (AC), Pinocembrin (PC), Pinobanksin (PB), and Apigenin (AP), have evolved as promising pharmacological agents in prevention of cancer (Jaganathan and Mandal, 2009).

Increasing numbers of antibiotic-resistant bacteria has made simple wounds become chronic and non-healing and as such honey provides alternative treatment options

(Sharp, 2009). Honey absorbs exudates released in wounds and devitalized tissue (Cutting, 2007). Honey is effective in recalcitrant surgical wounds (Cooper et al., 2001). It increases the rate of healing by stimulation of angiogenesis, granulation, and epithelialization (Molan, 2001a). In a randomized control trial, Manuka honey improved wound healing in patients with sloughy venous leg ulcers (Armstrong, 2009). Honey was shown to eradicate MRSA (Methylene resistant *Staphylococcus aureus*) infection in 70% of chronic venous ulcers (Gethin and Cowman, 2008). Honey is acidic and chronic non healing wounds have an elevated alkaline environment. Manuka honey dressings is associated with a statistically significant decrease in wound Ph (Gethin et al., 2008).

Chronic ulcers are risk factors in developing cancer. The most common is Marjolin's ulcer (Asuquo et al., 2009) and they are common in developing nations especially in rural areas with poor living conditions (Asuquo et al., 2007). This risk factor is related to chronic infections as most if not all chronic ulcers are non-healing because of persistent infections.

### Honey is a potential agent for controlling obesity

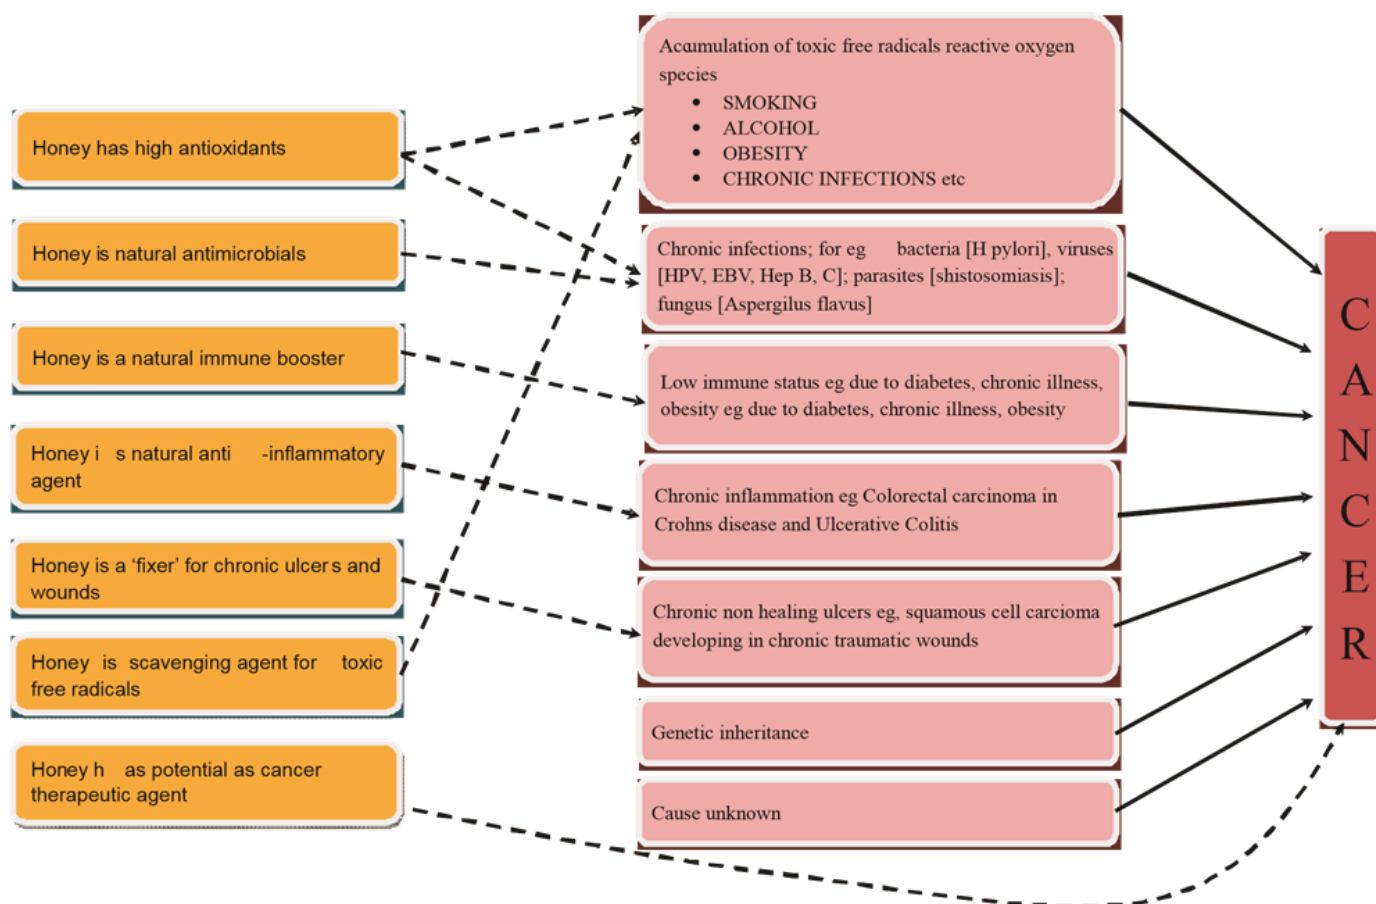

Obese individuals are at risk to develop cancer. There is a close link among obesity, a state of chronic low-level inflammation, and oxidative stress (Codoner-Franch et al., 2011). Obese subjects have an approximately 1.5-3.5-fold increased risk of developing cancers compared with normal-weight subjects (Pischon et al., 2008), (Rapp et al., 2008; Reeves et al., 2007) particularly endometrium (Bjorge et al., 2007; McCourt et al., 2007), breasts (Dogan et al., 2007; Ahn et al., 2007) and colorectal cancers (Moghaddam et al., 2007). Adipocytes have the ability to enhance the proliferation of colon cancer cells in vitro (Amemori et al., 2007). The greatest risk is for obese persons who are also diabetic, particular those whose body mass index is above 35 kg/m<sup>2</sup>. The increase in risk is by 93-fold in women and by 42-fold in men (Jung, 1997). One of the most common cancers noted in community that has high diabetics and obesity is colorectal cancer (Othman and Zin, 2008; Yang et al., 2005; Ahmed et al., 2006; Seow et al., 2006).

In a clinical study on 55 overweight or obese patients, the control group (17 subjects) received 70 g of sucrose daily for a maximum of 0 days and patients in the experimental group (38 subjects) received 70 g of natural honey for the same period. Results showed that honey caused a mild

reduction in body weight (1.3%) and body fat (1.1%) (Yaghoobi et al., 2008). Beneficial effect of honey on obesity is not well established thus far.

### Honey has potential use in 'cancer therapy'

Recent studies on human breast (Fauzi et al., 2011), cervical (Fauzi et al., 2011), oral (Ghashm et al., 2010) and osteocarcinoma (Ghashm et al., 2010) cancer cell lines using Malaysian jungle Tualang honey showed significant anticancer activity. Honey has also been shown to have antineoplastic activity in an experimental bladder model in vivo and in-vitro (Swellam et al., 2003). Honey is rich in flavonoids (Gomez-Caravaca et al., 2006; Jaganathan and Mandal, 2009). Flavonoids have created a lot of interests among researchers because of its anticancer properties. The mechanisms suggested are rather diverse such as inhibition of cell proliferation, induction of apoptosis (Ghashm et al., 2010) and cell cycle arrest (Pichichero et al., 2010) as well as inhibition of lipoprotein oxidation (Gheldof and Engeseth, 2002). It has been shown to induce early (Ghashm et al., 2010) and late apoptosis (Fauzi et al., 2011) and disruption of mitochondrial membrane potential (Fauzi et al., 2011). Breast cancers developed in rats after DMBA induction show smaller tumor size and lesser number of tumors compared to controls when the rats were fed on various doses of honey (manuscript under review for publication). Honey is thought to mediate these beneficial effects due to its major components such as chrysin (Woo et al., 2004) and other flavonoids (Jaganathan et al., 2010). These differences are explainable as honeys are of various floral sources and each floral source may exhibit different active compounds. Though honey has other substances of which the most predominant are a mixture of sugars (fructose, glucose, maltose and sucrose) (Aljadi and Kamaruddin, 2004) which itself is carcinogenic (Heuson et al., 1972), it is understandable that's its beneficial effect on cancer raises skeptics. The mechanism on how honey has anti-cancer effect is an area of great interest recently. There is a lot we can learn from nature (Moutsatsou, 2007). For example, phytochemicals, such as genistein, lycopene, curcumin, epigallocatechingallate, and resveratrol have been studied to be used for treatment of prostate cancer (Von Low et al., 2007). Phytoestrogens, constitute a group of plant-derived isoflavones and flavonoids and honey belongs to plant phytoestrogen (Moutsatsou, 2007; Zaid et al., 2010).

**Figure 2.** The diagrammatic relationship of honey and cancer (Key: solid line (→): parallel relationship; dotted line (---): inverse relationship)

Fairly recently, deeper understanding of honey and its anti-cancer effect was established (Ahmed and Othman 2017, Ahmed, Sulaiman et al. 2017, Ahmed, Sulaiman et al. 2018)

### Limitations

Although the effect of honey as anti-inflammatory, antimicrobial and promotion of chronic ulcer healing is extensively studied, its effect on other causes of cancers such as smoking, obesity and alcohol is not well studied thus far. One of its strong limitation is, It is difficult to standardize honey. Honey from different regions may have variations in its health benefits because its efficacy depends on the floral source. Isolating the active fragment of honey does not produce as good effect as total honey.

### Conclusion

There is now sizeable evidence that honey has a potential role in alleviating the causes of cancer and is thus a possible natural cancer vaccine. It is a natural immune booster, natural anti-inflammatory agent, natural antimicrobial agent, natural promoter for healing chronic ulcers and wounds and scavengers for toxic free radicals. Though it is essentially a sweet food and sugar is thought to be carcinogenic, its potential role in preventing cancer understandably raises skeptics. Improvement in immune status is key in prevention of cancer formation and honey has such potential. Recently, it has been shown to have direct anti-cancer effect on various cancer cell lines. Recent studies have established that wild honey has anti-cancer effect because it can cause shrinkage of cancer mass. With increasing number of people seeking therapy from nature, this area of research has recently gained attention.
